Hidden Watts

Prototype I

A single-player detective game about finding avoidable household electricity use.

Implemented features

Explore a furnished house with an animated character and furniture collisions.

Approach 11 electrical devices and press E to examine them.

Three complete cases load from JSON. Returning to the menu chooses another case.

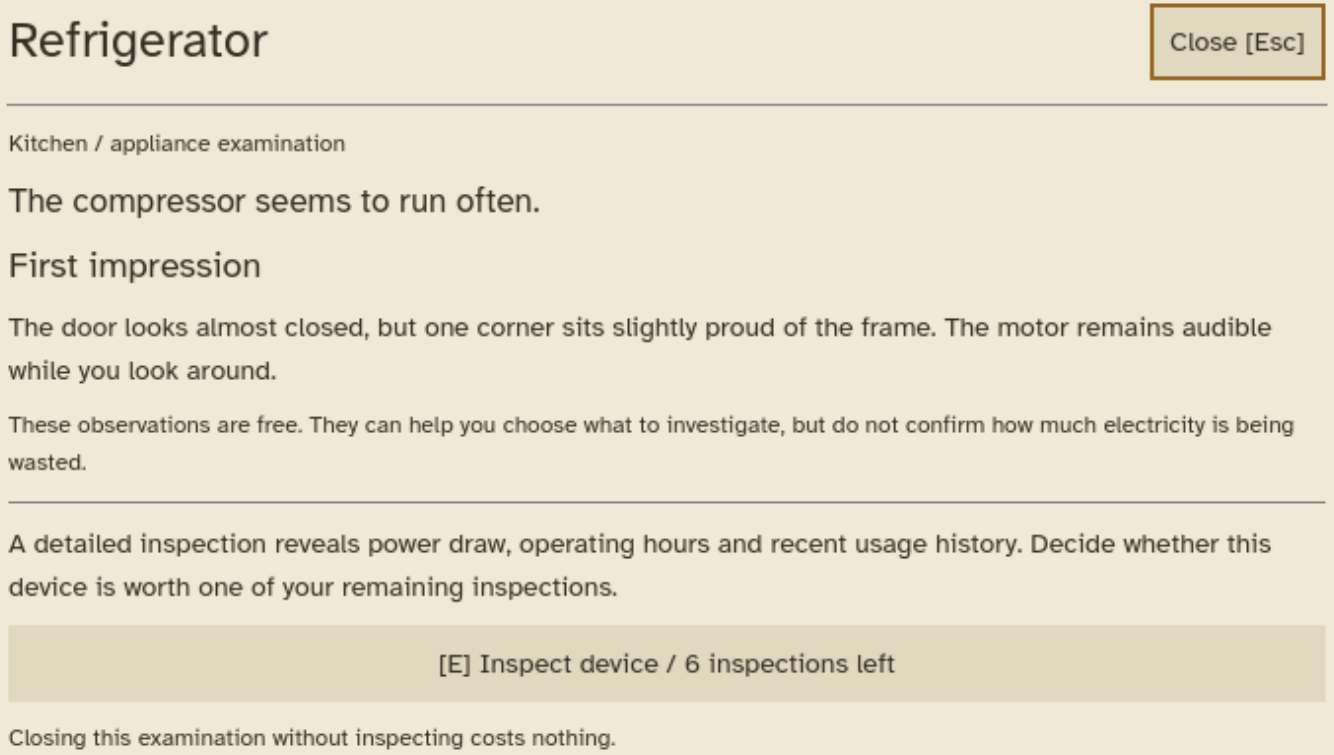

Choosing what to inspect

First impressions are free to read on every device.

Visible details and household habits suggest where to investigate.

Each case gives six detailed inspections to find three major problems.

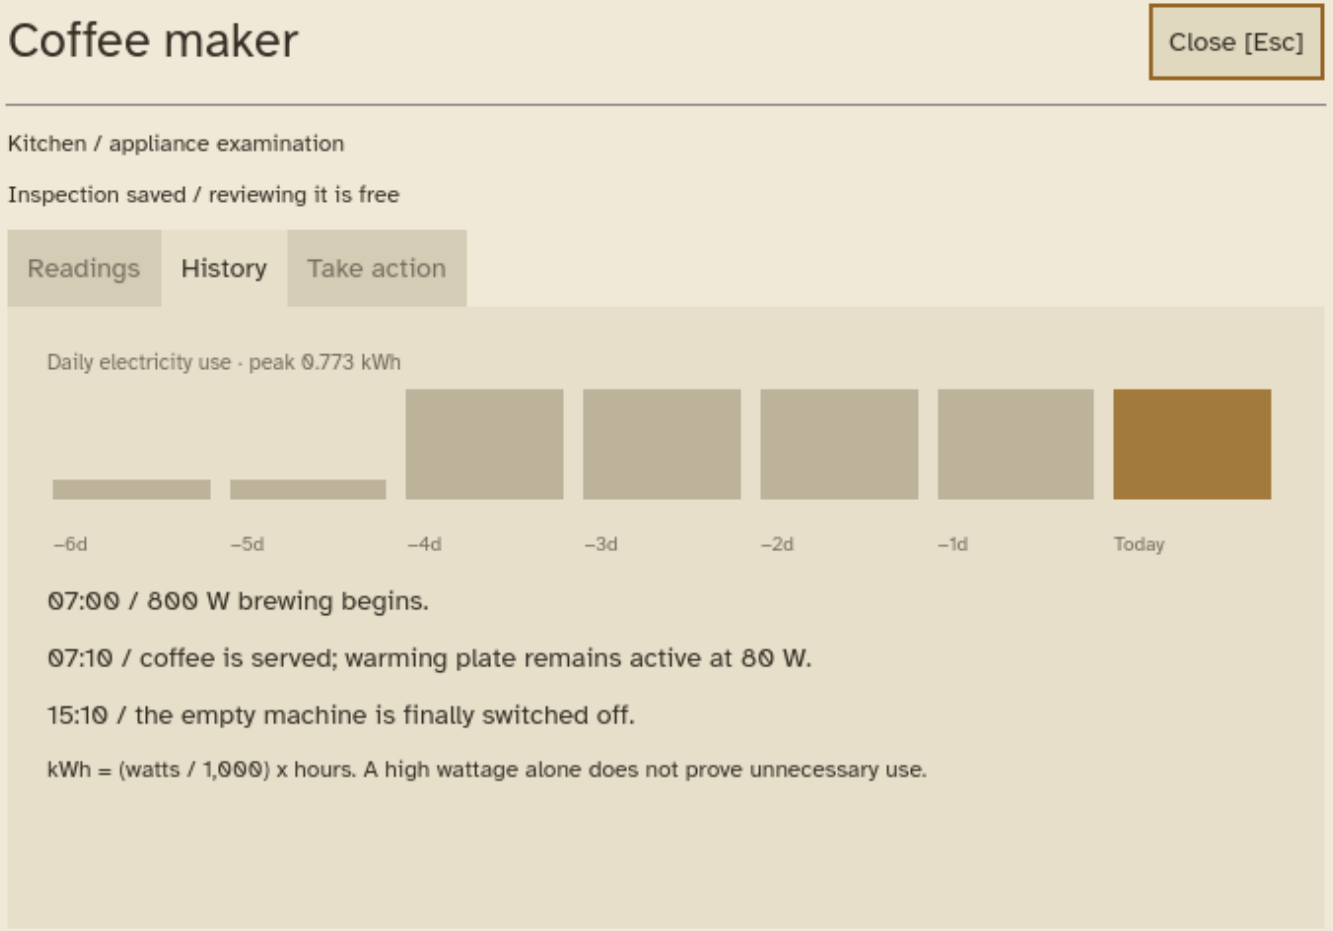

Evidence and corrective actions

An inspection reveals watts, operating time and recent usage history.

The player compares the readings with the household routine, then chooses an action.

Saved readings and case notes can be revisited without spending another inspection.

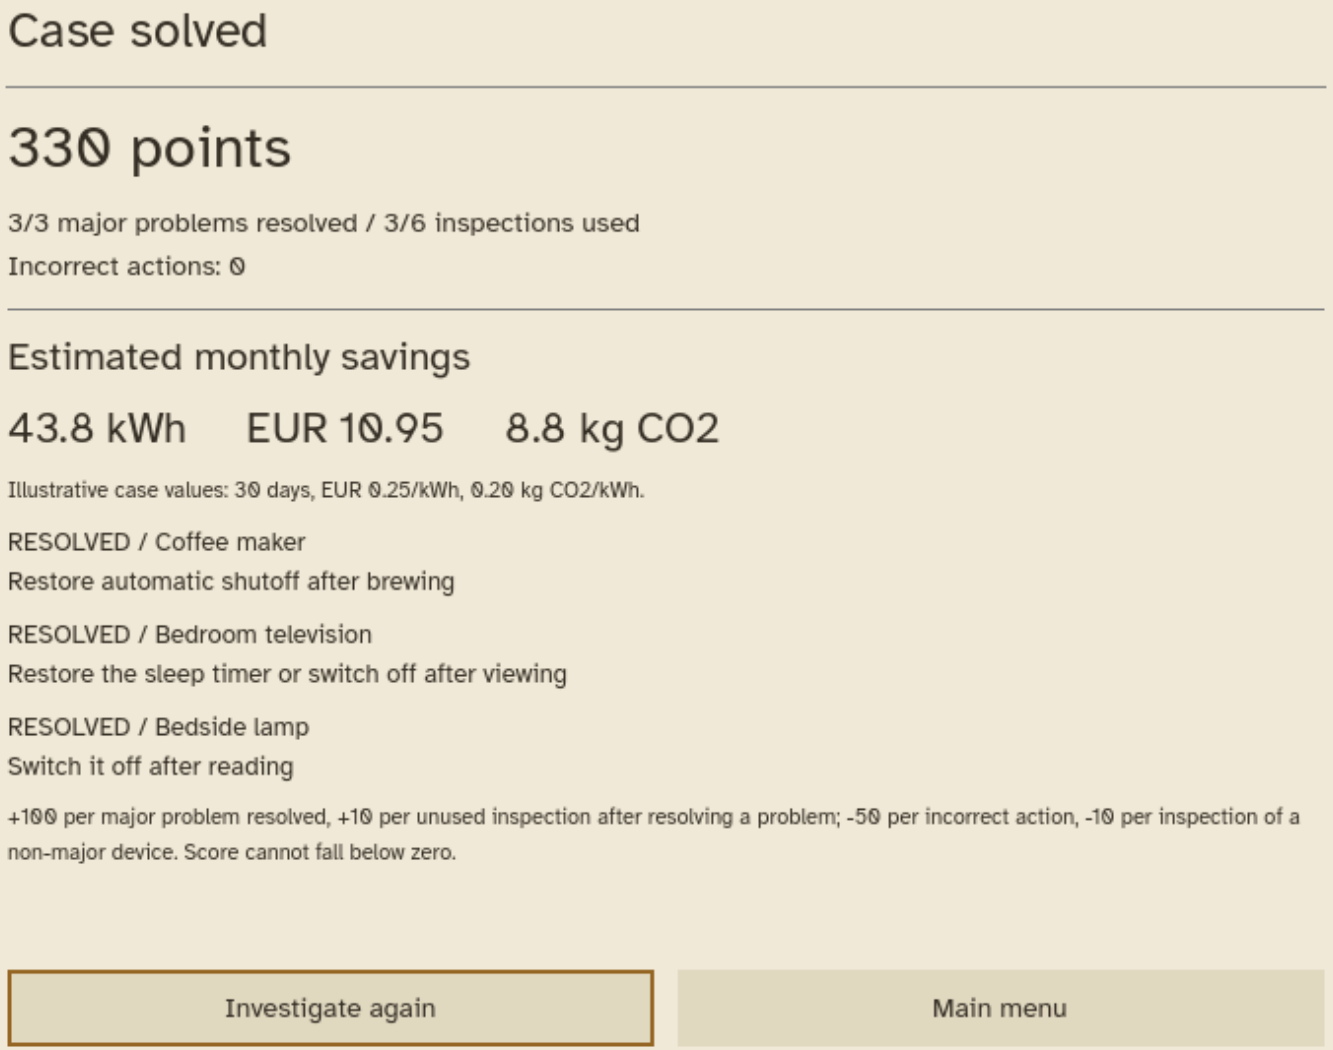

Social good in the gameplay

SDG 7: efficient electricity use
The player identifies avoidable use and chooses a practical correction.

SDG 13: climate action
Results connect electricity savings with estimated emissions avoided.

The game teaches that power draw and operating time both matter.

Prototype II plan

Planned next steps

Add household layouts and more varied cases.

Show clearer changes after a fix and add saved case progress.

UI improvements

AI usage

OpenAI Codex

Assisted with C# scripting, debugging, and code refactoring

Generated scenarios, device clues, and case data.
